USER DOCUMENTATION

GALAHAD Optimization Library version 4.1

## 1 SUMMARY

Given real  $n$  by  $n$  symmetric matrices  $\mathbf{H}$  and  $\mathbf{M}$  (with  $\mathbf{M}$  positive definite), a real  $n$  vector  $\mathbf{c}$  and scalars  $\Delta > 0$  and  $f_0$ , this package finds an **approximate minimizer of the quadratic objective function**  $\frac{1}{2}\mathbf{x}^T\mathbf{H}\mathbf{x} + \mathbf{c}^T\mathbf{x} + f_0$ , **where the vector  $\mathbf{x}$  is required to satisfy the constraint**  $\|\mathbf{x}\|_{\mathbf{M}} \leq \Delta$ , and where the  $\mathbf{M}$ -norm of  $\mathbf{x}$  is  $\|\mathbf{x}\|_{\mathbf{M}} = \sqrt{\mathbf{x}^T\mathbf{M}\mathbf{x}}$ . This problem commonly occurs as a trust-region subproblem in nonlinear optimization calculations. The method may be suitable for large  $n$  as no factorization of  $\mathbf{H}$  is required. Reverse communication is used to obtain matrix-vector products of the form  $\mathbf{H}\mathbf{z}$  and  $\mathbf{M}^{-1}\mathbf{z}$ .

The package may also be used to solve the related problem in which  $\mathbf{x}$  is instead required to satisfy the **equality constraint**  $\|\mathbf{x}\|_{\mathbf{M}} = \Delta$ .

**ATTRIBUTES — Versions:** GALAHAD\_GLTR\_single, GALAHAD\_GLTR\_double. **Uses:** GALAHAD\_SYMBOLS, GALAHAD\_SPACE, GALAHAD\_RAND, GALAHAD\_NORMS, GALAHAD\_ROOTS, GALAHAD\_SPECFILE, \*TTRF. **Date:** April 1997. **Origin:** N. I. M. Gould, Rutherford Appleton Laboratory. **Language:** Fortran 95 + TR 15581 or Fortran 2003.

## 2 HOW TO USE THE PACKAGE

Access to the package requires a USE statement such as

*Single precision version*

```
USE GALAHAD_GLTR_single
```

*Double precision version*

```
USE GALAHAD_GLTR_double
```

If it is required to use both modules at the same time, the derived types GLTR\_control\_type, GLTR\_inform\_type, GLTR\_data\_type, (Section 2.1) and the subroutines GLTR\_initialize, GLTR\_solve, GLTR\_terminate (Section 2.2) and GLTR\_read\_specfile (Section 2.6) must be renamed on one of the USE statements.

### 2.1 The derived data types

Three derived data types are accessible from the package.

#### 2.1.1 The derived data type for holding control parameters

The derived data type GLTR\_control\_type is used to hold controlling data. Default values may be obtained by calling GLTR\_initialize (see Section 2.2.1). The components of GLTR\_control\_type are:

**error** is a scalar variable of type default INTEGER, that holds the stream number for error messages. Printing of error messages in GLTR\_solve and GLTR\_terminate is suppressed if  $\text{error} \leq 0$ . The default is  $\text{error} = 6$ .

**out** is a scalar variable of type default INTEGER, that holds the stream number for informational messages. Printing of informational messages in GLTR\_solve is suppressed if  $\text{out} < 0$ . The default is  $\text{out} = -1$ .

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

`print_level` is a scalar variable of type default `INTEGER`, that is used to control the amount of informational output which is required. No informational output will occur if `print_level`  $\leq 0$ . If `print_level` = 1 a single line of output will be produced for each iteration of the process. If `print_level`  $\geq 2$  this output will be increased to provide significant detail of each iteration. The default is `print_level` = 0.

`itmax` is a scalar variable of type default `INTEGER`, that holds the maximum number of iterations which will be allowed in `GLTR_solve`. If `itmax` is set to a negative number, it will be reset by `GLTR_solve` to  $n$ . The default is `itmax` = -1.

`lanczos_itmax` is a scalar variable of type default `INTEGER`, that holds the maximum number of iterations that may be performed when the iterates encounter the boundary of the constraint. If `lanczos_itmax` is set to a negative number, it will be reset by `GLTR_solve` to  $n$ . The default is `lanczos_itmax` = -1.

`unitm` is a scalar variable of type default `LOGICAL`, that must be set `.TRUE.` if the matrix  $\mathbf{M}$  is the identity matrix, and `.FALSE.` otherwise. The default is `unitm` = `.TRUE.`.

`extra_vectors` is a scalar variable of type default `INTEGER`, that specifies the number of additional vectors of length  $n$  that will be allocated to try to speed up the computation if the constraint boundary is encountered. The default is `extra_vectors` = 0.

`steihaug_toint` is a scalar variable of type default `LOGICAL`, which must be set `.TRUE.` if the algorithm is required to stop at the first point on the boundary of the constraint that is encountered, and `.FALSE.` if the constraint boundary is to be investigated further. Setting `steihaug_toint` to `.TRUE.` can reduce the amount of computation at the expense of obtaining a poorer estimate of the solution. The default is `steihaug_toint` = `.FALSE.`.

`boundary` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user believes that the solution will occur on the constraint boundary, and `.FALSE.` otherwise. A correct setting of `boundary` may reduce the amount of computation performed. The default is `boundary` = `.FALSE.`.

`equality_problem` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user requires that the solution occur on the constraint boundary (i.e., that the inequality constraint be replaced by  $\|\mathbf{x}\|_{\mathbf{M}} = \Delta$ ), and `.FALSE.` otherwise. The default is `equality_problem` = `.FALSE.`.

`space_critical` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user wishes the package to allocate as little internal storage as possible, and `.FALSE.` otherwise. The package may be more efficient if `space_critical` is set `.FALSE.`. The default is `space_critical` = `.FALSE.`.

`deallocate_error_fatal` is a scalar variable of type default `LOGICAL`, that may be set `.TRUE.` if the user wishes the package to return to the user in the unlikely event that an internal array deallocation fails, and `.FALSE.` if the package should be allowed to try to continue. The default is `deallocate_error_fatal` = `.FALSE.`.

`stop_relative` and `stop_absolute` are scalar variables of type `REAL` (double precision in `GALAHAD_GLTR_double`), that holds the relative and absolute convergence tolerances (see Section 4). The computed solution  $\mathbf{x}$  is accepted by `GLTR_solve` if the computed value of  $\|\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c}\|_{\mathbf{M}^{-1}}$  is less than or equal to  $\max(\|\mathbf{c}\|_{\mathbf{M}^{-1}} * \text{stop\_relative}, \text{stop\_absolute})$ , where  $\lambda$  is an estimate of the Lagrange multiplier associated with the trust-region constraint. The defaults are `stop_relative` =  $\sqrt{u}$  and `stop_absolute` = 0.0, where  $u$  is `EPSILON(1.0)` (`EPSILON(1.0D0)` in `GALAHAD_GLTR_double`).

`f_min` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that specifies the smallest value of the objective function that is allowed without regarding the problem as being unbounded from below. The default is `f_min` = `-HUGE(1.0)/2.0` (`-HUGE(1.0D0)/2.0D0` in `GALAHAD_GLTR_double`).

`fraction_opt` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that specifies the fraction of the optimal value which is to be considered acceptable by the algorithm. A negative value is considered to be zero, and a value of larger than one is considered to be one. Reducing `fraction_opt` below

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

one will result in a reduction of the computation performed at the expense of an inferior optimal value. The default is `fraction_opt = 1.0`.

`f_0` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that gives the value of the constant term  $f_0$  in the quadratic objective function. This value has no effect on the computed minimizer  $\mathbf{x}$ . The default is `f_0 = 0.0`.

`rminvr_zero` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that gives the smallest value that the square of the  $\mathbf{M}$ -norm of the gradient of the objective function may be before it is considered to be zero. The default is `rminvr_zero = 10  $\mu$` , where  $\mu$  is `EPSILON(1.0)` (`EPSILON(1.0D0)` in `GALAHAD_GLTR_double`).

`prefix` is a scalar variable of type default `CHARACTER` and length 30, that may be used to provide a user-selected character string to preface every line of printed output. Specifically, each line of output will be prefaced by the string `prefix(2:LEN(TRIM(prefix))-1)`, thus ignoring the first and last non-null components of the supplied string. If the user does not want to preface lines by such a string, they may use the default `prefix = ""`.

### 2.1.2 The derived data type for holding informational parameters

The derived data type `GLTR_inform_type` is used to hold parameters that give information about the progress and needs of the algorithm. The components of `GLTR_inform_type` are:

`status` is a scalar variable of type default `INTEGER`, that gives the current status of the algorithm. See Sections 2.3 and 2.4 for details.

`alloc_status` is a scalar variable of type default `INTEGER`, that gives the status of the last internal array allocation or deallocation. This will be 0 if `status = 0`.

`bad_alloc` is a scalar variable of type default `CHARACTER` and length 80, that gives the name of the last internal array for which there were allocation or deallocation errors. This will be the null string if `status = 0`.

`multiplier` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that holds the value of the Lagrange multiplier associated with the constraint.

`mnormx` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that holds the current value of  $\|\mathbf{x}\|_{\mathbf{M}}$ .

`leftmost` is a scalar variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that holds an estimate of the leftmost eigenvalue of the matrix pencil  $(\mathbf{H}, \mathbf{M})$ .

`iter` is a scalar variable of type default `INTEGER`, that holds the current number of Lanczos vectors used.

`iter_pass2` is a scalar variable of type default `INTEGER`, that holds the current number of Lanczos vectors used in the second pass.

`negative_curvature` is a scalar variable of type default `LOGICAL`, that is set `.TRUE.` if  $\mathbf{H}$  has been found to be indefinite during the calculation and `.FALSE.` otherwise.

For backward compatibility with an earlier version of the package, there is an equivalent type `GLTR_info_type`, and the two names may be used interchangeably.

### 2.1.3 The derived data type for holding problem data

The derived data type `GLTR_data_type` is used to hold all the data for a particular problem between calls of `GLTR` procedures. This data should be preserved, untouched, from the initial call to `GLTR_initialize` to the final call to `GLTR_terminate`.

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

## 2.2 Argument lists and calling sequences

There are three procedures for user calls (see Section 2.6 for further features):

1. The subroutine `GLTR_initialize` is used to set default values, and initialize private data.
2. The subroutine `GLTR_solve` is called repeatedly to solve the problem. On each exit, the user may be expected to provide additional information and, if necessary, re-enter the subroutine.
3. The subroutine `GLTR_terminate` is provided to allow the user to automatically deallocate array components of the private data, allocated by `GLTR_solve`, at the end of the solution process. It is important to do this if the data object is re-used for another problem since `GLTR_initialize` cannot test for this situation, and any existing associated targets will subsequently become unreachable.

We use square brackets [ ] to indicate OPTIONAL arguments.

### 2.2.1 The initialization subroutine

Default values are provided as follows:

```
CALL GLTR_initialize( data, control, inform )
```

`data` is a scalar `INTENT(INOUT)` argument of type `GLTR_data_type` (see Section 2.1.3). It is used to hold data about the problem being solved.

`control` is a scalar `INTENT(OUT)` argument of type `GLTR_control_type` (see Section 2.1.1). On exit, `control` contains default values for the components as described in Section 2.1.1. These values should only be changed after calling `GLTR_initialize`.

`inform` is a scalar `INTENT(OUT)` argument of type `GLTR_inform_type` (see Section 2.1.2). A successful call to `GLTR_initialize` is indicated when the component status has the value 0. For other return values of status, see Section 2.4.

### 2.2.2 The optimization problem solution subroutine

The optimization problem solution algorithm is called as follows:

```
CALL GLTR_solve( n, radius, f, X, R, VECTOR, data, control, inform )
```

`n` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set to the number of unknowns,  $n$ . **Restriction:**  $n > 0$ .

`radius` is a scalar `INTENT(IN)` variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that must be set on initial entry to the value of the radius of the quadratic constraint,  $\Delta$ . **Restriction:**  $\Delta > 0$ .

`f` is a scalar `INTENT(INOUT)` variable of type default `REAL` (double precision in `GALAHAD_GLTR_double`), that holds an estimate of the optimal value of the quadratic objective function. On initial entry, `f` need not be set. It must not be changed between entries. On exit, `f` contains the current best estimate of the optimal objective value.

`X` is an array `INTENT(INOUT)` argument of dimension  $n$  and type default `REAL` (double precision in `GALAHAD_GLTR_double`), that holds an estimate of the solution  $\mathbf{x}$  of the linear system. On initial entry, `X` need not be set. It must not be changed between entries. On exit, `X` contains the current best estimate of the solution.

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

`R` is an array `INTENT(INOUT)` argument of dimension `n` and type default `REAL` (double precision in `GALAHAD_GLTR_double`), that is used to hold the gradient  $\mathbf{H}\mathbf{x} + \mathbf{c}$  of the objective function at the current estimate of the solution. On initial entry, `R` must contain the vector `c`. If `inform%status = 5` on exit, it must be reset to `c`; otherwise it must be left unchanged. On exit, `R` contains the gradient of the objective function at the current best estimate of the solution.

`VECTOR` is an array `INTENT(INOUT)` argument of dimension `n` and type default `REAL` (double precision in `GALAHAD_GLTR_double`), that is used to pass information from and to `GLTR_solve`, as explained in Section 2.3. On initial entry, `VECTOR` need not be set. On exit, the actual content of the array depends on the value of the parameter `inform%status` (see Section 2.3).

`data` is a scalar `INTENT(INOUT)` argument of type `GLTR_data_type` (see Section 2.1.3). It is used to hold data about the problem being solved. It must not have been altered **by the user** since the last call to `GLTR_initialize`.

`control` is a scalar `INTENT(IN)` argument of type `GLTR_control_type`. (see Section 2.1.1). Default values may be assigned by calling `GLTR_initialize` prior to the first call to `GLTR_solve`.

`inform` is a scalar `INTENT(INOUT)` argument of type `GLTR_inform_type` (see Section 2.1.2). On initial entry, the component `status` must be set to 1. The remaining components need not be set. A successful call to `GLTR_solve` is indicated when the component `status` has the value 0. For other return values of `status`, see Sections 2.3 and 2.4.

### 2.2.3 The termination subroutine

All previously allocated arrays are deallocated as follows:

```
CALL GLTR_terminate( data, control, inform )
```

`data` is a scalar `INTENT(INOUT)` argument of type `GLTR_data_type` exactly as for `GLTR_solve` that must not have been altered **by the user** since the last call to `GLTR_initialize`. On exit, array components will have been deallocated.

`control` is a scalar `INTENT(IN)` argument of type `GLTR_control_type` exactly as for `GLTR_solve`.

`inform` is a scalar `INTENT(OUT)` argument of type `GLTR_inform_type` exactly as for `GLTR_solve`. Only the component `status` will be set on exit, and a successful call to `GLTR_terminate` is indicated when this component `status` has the value 0. For other return values of `status`, see Section 2.4.

## 2.3 Reverse communication

A positive value of `inform%status` on exit from `GLTR_solve` indicates that the user needs to take appropriate action before re-entering the subroutine. Possible values are:

2. The user must perform the preconditioning operation

$$\mathbf{y} := \mathbf{M}^{-1}\mathbf{z},$$

and recall `GLTR_solve`. The vector `z` is available in the array `VECTOR`, and the result `y` must be placed in `VECTOR`. No argument except `VECTOR` should be altered before recalling `GLTR_solve`. This return can only occur when `control%unitm` is `.FALSE..`

3. The user must perform the matrix-vector product

$$\mathbf{y} := \mathbf{H}\mathbf{z}$$

and recall `GLTR_solve`. The vector `z` is available in the array `VECTOR`, and the result `y` must be placed in `VECTOR`. No argument except `VECTOR` should be altered before recalling `GLTR_solve`.

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

5. The user should reset `R` to `c` and recall `GLTR_solve`. No argument except `R` should be altered before recalling `GLTR_solve`.

## 2.4 Warning and error messages

A negative value of `inform%status` on exit from `GLTR_solve` or `GLTR_terminate` indicates that an error might have occurred. No further calls should be made until the error has been corrected. Possible values are:

- 1. An allocation error occurred. A message indicating the offending array is written on unit `control%error`, and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 2. A deallocation error occurred. A message indicating the offending array is written on unit `control%error` and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 3. (`GLTR_solve` only) One of the restrictions `n > 0` or `radius > 0` has been violated.
- 15. (`GLTR_solve` only) The matrix **M** appears not to be positive definite.
- 18. (`GLTR_solve` only) More than `control%itmax` iterations have been performed without obtaining convergence.
- 30. (`GLTR_solve` only) The constraint boundary has been encountered when the input value of `control%steihaug_toint` was set `.TRUE.`. The solution is unlikely to have achieved the accuracy required by `control%stop_relative` and `control%stop_absolute`.
- 44 (`GLTR_solve` only) An objective function value smaller than `control%f_min` has been detected.

## 2.5 Re-entry with a new value of $\Delta$

It commonly happens that, having solved the problem for a particular value of the radius  $\Delta$ , a user now wishes to solve the problem for a different value of  $\Delta$ . Rather than restarting the calculation with `inform%status = 1`, a useful approximation may be found resetting `radius` to the new required value and `R` to `c`, and recalling `GLTR_solve` with `inform%status = 4` and the remaining arguments unchanged. This will determine the best solution within the Krylov space investigated in the previous minimization (see Section 4).

## 2.6 Further features

In this section, we describe an alternative means of setting control parameters, that is components of the variable `control` of type `GLTR_control_type` (see Section 2.1.1), by reading an appropriate data specification file using the subroutine `GLTR_read_specfile`. This facility is useful as it allows a user to change GLTR control parameters without editing and recompiling programs that call GLTR.

A specification file, or `specfile`, is a data file containing a number of "specification commands". Each command occurs on a separate line, and comprises a "keyword", which is a string (in a close-to-natural language) used to identify a control parameter, and an (optional) "value", which defines the value to be assigned to the given control parameter. All keywords and values are case insensitive, keywords may be preceded by one or more blanks but values must not contain blanks, and each value must be separated from its keyword by at least one blank. Values must not contain more than 30 characters, and each line of the `specfile` is limited to 80 characters, including the blanks separating keyword and value.

The portion of the specification file used by `GLTR_read_specfile` must start with a "BEGIN GLTR" command and end with an "END" command. The syntax of the `specfile` is thus defined as follows:

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

```
( .. lines ignored by GLTR_read_specfile .. )
BEGIN GLTR
  keyword      value
  .....      .....
  keyword      value
END
( .. lines ignored by GLTR_read_specfile .. )
```

where keyword and value are two strings separated by (at least) one blank. The “BEGIN GLTR” and “END” delimiter command lines may contain additional (trailing) strings so long as such strings are separated by one or more blanks, so that lines such as

```
BEGIN GLTR SPECIFICATION
```

and

```
END GLTR SPECIFICATION
```

are acceptable. Furthermore, between the “BEGIN GLTR” and “END” delimiters, specification commands may occur in any order. Blank lines and lines whose first non-blank character is ! or \* are ignored. The content of a line after a ! or \* character is also ignored (as is the ! or \* character itself). This provides an easy manner to “comment out” some specification commands, or to comment specific values of certain control parameters.

The value of a control parameters may be of three different types, namely integer, logical or real. Integer and real values may be expressed in any relevant Fortran integer and floating-point formats (respectively). Permitted values for logical parameters are “ON”, “TRUE”, “.TRUE.”, “T”, “YES”, “Y”, or “OFF”, “NO”, “N”, “FALSE”, “.FALSE.” and “F”. Empty values are also allowed for logical control parameters, and are interpreted as “TRUE”.

The specification file must be open for input when `GLTR_read_specfile` is called, and the associated device number passed to the routine in `device` (see below). Note that the corresponding file is `REWINDed`, which makes it possible to combine the specifications for more than one program/routine. For the same reason, the file is not closed by `GLTR_read_specfile`.

### 2.6.1 To read control parameters from a specification file

Control parameters may be read from a file as follows:

```
CALL GLTR_read_specfile( control, device )
```

`control` is a scalar `INTENT(INOUT)` argument of type `GLTR_control_type` (see Section 2.1.1). Default values should have already been set, perhaps by calling `GLTR_initialize`. On exit, individual components of `control` may have been changed according to the commands found in the specfile. Specfile commands and the component (see Section 2.1.1) of `control` that each affects are given in Table 2.1.

`device` is a scalar `INTENT(IN)` argument of type default `INTEGER`, that must be set to the unit number on which the specfile has been opened. If `device` is not open, `control` will not be altered and execution will continue, but an error message will be printed on unit `control%error`.

## 2.7 Information printed

If `control%print_level` is positive, information about the progress of the algorithm will be printed on unit `control%out`. If `control%print_level = 1`, a single line of output will be produced for each iteration of the process. So long as the current estimate lies within the constraint boundary, this will include the iteration number, the value of the objective function, the norm of the gradient, the step taken, the two-norm of the latest search direction, the norm  $\|x\|_M$ ,

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

command	component of control	value type
error-printout-device	%error	integer
printout-device	%out	integer
print-level	%print_level	integer
maximum-number-of-iterations	%itmax	integer

Table 2.1: Specfile commands and associated components of control.

and the curvature of  $\mathbf{H}$  observed along the current search direction (see Section 4). A further message will be printed if the constraint boundary is encountered during the current iteration. Thereafter, the one-line summary will record the iteration number, the value of the objective function, the norm of the gradient of the Lagrangian,  $\|\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c}\|_{\mathbf{M}^{-1}}$ , the value of the Lagrange multiplier, the number of iterations taken to solve the “tridiagonal” subproblem and the exit status from this calculation (once again, see Section 4). If  $\text{control}\% \text{print\_level} \geq 2$ , this output will be increased to provide significant detail of each iteration. This extra output includes a complete history of the inner iteration required to solve the “tridiagonal” subproblem, and records the leftmost eigenvalue of  $\mathbf{T}_k$  (if needed), along with the estimates of the Lagrange multipliers and the norm  $\|\mathbf{x}\|_{\mathbf{M}}$  generated during the inner iteration.

### 3 GENERAL INFORMATION

**Use of common:** None.

**Workspace:** Provided automatically by the module.

**Other routines called directly:** GLTR\_solve calls the LAPACK subroutine \*PTTRF, where \* is S for the default real version and D for the double precision version.

**Other modules used directly:** GLTR\_solve calls the GALAHAD packages GALAHAD\_SYMBOLS, GALAHAD\_SPACE, GALAHAD\_RAND, GALAHAD\_NORMS, GALAHAD\_ROOTS and GALAHAD\_SPECFILE.

**Input/output:** Output is under control of the arguments `control%error`, `control%out` and `control%print_level`.

**Restrictions:**  $n > 0$ ,  $\Delta > 0$ .

**Portability:** ISO Fortran 95 + TR 15581 or Fortran 2003. The package is thread-safe.

---

**All use is subject to the conditions of the GNU Lesser General Public License version 3.**  
**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

## 4 METHOD

The required solution  $\mathbf{x}$  necessarily satisfies the optimality condition  $\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c} = 0$ , where  $\lambda \geq 0$  is a Lagrange multiplier corresponding to the constraint  $\|\mathbf{x}\|_{\mathbf{M}} \leq \Delta$ . In addition, the matrix  $\mathbf{H} + \lambda\mathbf{M}$  will be positive definite.

The method is iterative. Starting with the vector  $\mathbf{M}^{-1}\mathbf{c}$ , a matrix of Lanczos vectors is built one column at a time so that the  $k$ -th column is generated during iteration  $k$ . These columns span a so-called Krylov space. The resulting  $n$  by  $k$  matrix  $\mathbf{Q}_k$  has the property that  $\mathbf{Q}_k^T \mathbf{H} \mathbf{Q}_k = \mathbf{T}_k$ , where  $\mathbf{T}_k$  is tridiagonal. An approximation to the required solution may then be expressed formally as

$$\mathbf{x}_{k+1} = \mathbf{Q}_k \mathbf{y}_k$$

where  $\mathbf{y}_k$  solves the “tridiagonal” subproblem of minimizing

$$\frac{1}{2} \mathbf{y}^T \mathbf{T}_k \mathbf{y} + \|\mathbf{c}\|_{\mathbf{M}^{-1}} \mathbf{e}_1^T \mathbf{y} \text{ subject to the constraint } \|\mathbf{y}\|_2 \leq \Delta, \quad (4.1)$$

and where  $\mathbf{e}_1$  is the first unit vector.

If the solution to (4.1) lies interior to the constraint, the required solution  $\mathbf{x}_{k+1}$  may simply be found as the  $k$ -th (preconditioned) conjugate-gradient iterate. This solution can be obtained without the need to access the whole matrix  $\mathbf{Q}_k$ . These conjugate-gradient iterates increase in  $\mathbf{M}$ -norm, and thus once one of them exceeds  $\Delta$  in  $\mathbf{M}$ -norm, the solution must occur on the constraint boundary. Thereafter, the solution to (4.1) is less easy to obtain, but an efficient inner iteration to solve (4.1) is nonetheless achievable because  $\mathbf{T}_k$  is tridiagonal. It is possible to observe the optimality measure  $\|\mathbf{H}\mathbf{x} + \lambda\mathbf{M}\mathbf{x} + \mathbf{c}\|_{\mathbf{M}^{-1}}$  without computing  $\mathbf{x}_{k+1}$ , and thus without needing  $\mathbf{Q}_k$ . Once this measure is sufficiently small, a second pass is required to obtain the estimate  $\mathbf{x}_{k+1}$  from  $\mathbf{y}_k$ . As this second pass is an additional expense, a record is kept of the optimal objective function values for each value of  $k$ , and the second pass is only performed so far as to ensure a given fraction of the final optimal objective value. Large savings may be made in the second pass by choosing the required fraction to be significantly smaller than one.

A cheaper alternative is to use the Steihaug-Toint strategy, which is simply to stop at the first boundary point encountered along the piecewise linear path generated by the conjugate-gradient iterates. Note that if  $\mathbf{H}$  is significantly indefinite, this strategy often produces a far from optimal point, but is effective when  $\mathbf{H}$  is positive definite or almost so.

## 5 EXAMPLE OF USE

Suppose we wish to solve a problem in 10,000 unknowns, whose data is

$$\mathbf{H} = \begin{pmatrix} -2 & 1 & & & \\ 1 & -2 & . & & \\ & . & . & . & \\ & & . & -2 & 1 \\ & & & 1 & -2 \end{pmatrix}, \quad \mathbf{M} = \begin{pmatrix} 2 & & & & \\ & 2 & & & \\ & & . & & \\ & & & 2 & \\ & & & & 2 \end{pmatrix} \text{ and } \mathbf{c} = \begin{pmatrix} 1 \\ 1 \\ . \\ 1 \\ 1 \end{pmatrix},$$

with a radius  $\Delta = 10$ . Then we may use the following code

```
PROGRAM GALAHAD_GLTR_EXAMPLE ! GALAHAD 4.3 - 2022-11-26 AT 09:50 GMT.
USE GALAHAD_GLTR_DOUBLE ! double precision version
IMPLICIT NONE
INTEGER, PARAMETER :: wp = KIND( 1.0D+0 ) ! set precision
REAL ( KIND = wp ), PARAMETER :: one = 1.0_wp, two = 2.0_wp
```

---

**See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.**

```

INTEGER, PARAMETER :: n = 10000                ! problem dimension
INTEGER :: i
REAL ( KIND = wp ) :: f, radius = 10.0_wp ! radius of ten
REAL ( KIND = wp ), DIMENSION( n ) :: X, R, VECTOR, H_vector
TYPE ( GLTR_data_type ) :: data
TYPE ( GLTR_control_type ) :: control
TYPE ( GLTR_inform_type ) :: inform
CALL GLTR_initialize( data, control, inform ) ! Initialize control parameters
! control%print_level = 1
control%unitm = .FALSE.                ! M is not the identity matrix
R = one                                ! The linear term is a vector of ones
inform%status = 1
DO                                     ! Iteration to find the minimizer
CALL GLTR_solve( n, radius, f, X, R, VECTOR, data, control, inform )
SELECT CASE( inform%status ) ! Branch as a result of inform%status
CASE( 2 )                        ! Form the preconditioned gradient
    VECTOR = VECTOR / two        ! Preconditioner is two times identity
CASE ( 3 )                       ! Form the matrix-vector product
    H_vector( 1 ) = - two * VECTOR( 1 ) + VECTOR( 2 )
    DO i = 2, n - 1
        H_vector( i ) = VECTOR( i - 1 ) - two * VECTOR( i ) + VECTOR( i + 1 )
    END DO
    H_vector( n ) = VECTOR( n - 1 ) - two * VECTOR( n )
    VECTOR = H_vector
CASE ( 5 )                        ! Restart
    R = one
CASE ( - 30, 0 ) ! Successful return
    WRITE( 6, "( I6, ' iterations. Solution and Lagrange multiplier = ', &
& 2ES12.4 )" ) inform%iter + inform%iter_pass2, f, inform%multiplier
    CALL GLTR_terminate( data, control, inform ) ! delete internal workspace
    EXIT
CASE DEFAULT                     ! Error returns
    WRITE( 6, "( ' GLTR_solve exit status = ', I6 ) " ) inform%status
    CALL GLTR_terminate( data, control, inform ) ! delete internal workspace
    EXIT
END SELECT
END DO
END PROGRAM GALAHAD_GLTR_EXAMPLE

```

This produces the following output:

```

11 iterations. Solution and Lagrange multiplier = -7.0711E+02  7.0712E+00

```
